- Sorting Algorithms

# Algorithms

# What is an Algorithm?

- It is a step by step approach to solve a particular problem.
- It gives a crisp solution.
- It can be understood by non-technical people as well.
- It's free of programming language constructs.
- There can be multiple possible algorithm to solve a given problem.

# What is an Algorithmic Analysis?

- It is a step by step approach to solve a particular problem.
- It gives a crisp solution.
- It helps in the identification of optimal algorithm
- It helps in understanding the trade-off of time and space requirement.

# Algorithmic Analysis- Types

- There are different types of algorithmic analysis
  - Best case
  - Average case
  - Worst case
- Worst case is computed always for the analysis as it dictates maximum resource requirements.

# Time Complexity

- It determines the total number of unit operations to be undertaken to solve a particular problem.
- Unit operation is an operation that is independent and can't be broken down in simpler operation.
- It is independent of architecture.
- It is computed on the basis of algorithm itself.
- It's a high priority criteria in optimal algorithm selection.

# Time Complexity- Example 1

# Time Complexity- Example 2

# Space Complexity

- It determines the total space to be allocated in order to solve a particular problem.
- It is the extra memory that an algorithm needs for its implementation.
- It involves the memory of computers.
- It's a low priority criteria in optimal algorithm selection.

# Space Complexity- Example 1

# Space Complexity- Example 2

# Recursion

# What is Recursion?

- Recursion is about function calling itself.
- It comes intuitive when a function is breakable into subproblems.
- There are many data structures which are recursive in nature.

# Steps of recursion

- Base condition
- Logic
- Recursive call

# Recursion vs Iteration

- Recursion is about function calling itself whereas iteration can't call itself.
- There is always some space complexity associated with recursion.
- Recursion implicitly works with stack data structure. There is no such requirement in iteration.
- Recursion is slower than iteration.

# Tail Recursion

- Here the recursive call is the last step of implementation.
- This is a faster approach of recursion.
- No activation record maintenance is required here.

# Tail Recursion- Example

# Non-Tail Recursion

- Here the recursive call is the not the last step of implementation.
- This is a slower approach of recursion.
- Activation record maintenance is required here.

# Non-Tail Recursion- Example

# Direct Recursion

- When call within function call is made on the same function.
- ```
f(){  
    f()  
}
```
- Only one function is involved here.

# Direct Recursion- Example

# Indirect Recursion

- When call within function call is made on the different function.
- ```
f1(){  
    f2()  
}  
  
f2(){  
    f1()  
}
```
- More than one functions are involved here.

# Indirect Recursion- Example

# Recursion- Time Complexity

# Recursion- Space Complexity

# Binary Search Algorithm

# What is Binary Search?

- Binary Search is one of the searching techniques.
- It can be used on sorted array.
- This searching technique follows the divide and conquer strategy and search space always reduces to half in every iteration.
- This is a very efficient technique for searching but it needs some order on which partition of the array will occur.

# Binary Search - Iterative Algorithm

```
binarySearch(arr, size)
    loop until beg is not equal to end
        midIndex = (beg + end)/2
        if (item == arr[midIndex] )
            return midIndex
        else if (item > arr[midIndex] )
            beg = midIndex + 1
        else
            end = midIndex - 1
```

# Binary Search - Recursive Algorithm

```
binarySearch(arr, item, beg, end)
    if beg <= end
        midIndex = (beg + end) / 2
        if item == arr[midIndex]
            return midIndex
        else if item < arr[midIndex]
            return binarySearch(arr, item, midIndex + 1, end)
        else
            return binarySearch(arr, item, beg, midIndex - 1)
    return -1
```

# Binary Search - Demonstration

Item to be searched=20

input:

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 11 | 16 | 20 | 23 |

beg=0, end=4, mid=2

|    |    |           |    |    |
|----|----|-----------|----|----|
| 0  | 1  | <b>2</b>  | 3  | 4  |
| 10 | 11 | <b>16</b> | 20 | 23 |

beg=3, end=4, mid=3

|    |    |    |           |    |
|----|----|----|-----------|----|
| 0  | 1  | 2  | <b>3</b>  | 4  |
| 10 | 11 | 16 | <b>20</b> | 23 |

Element found at index 3, Hence 3 will get returned

# Binary Search – Implementation 1

```
int binarySearch(int arr[], int item, int beg, int end) {  
    while (beg <= end) {  
        int midIndex = beg + (end - beg) / 2;  
        if (arr[midIndex] == item)  
            return midIndex;  
        if (arr[midIndex] > item)  
            beg = midIndex + 1;  
        else  
            end = midIndex - 1;  
    }  
    return -1;  
}
```

# Binary Search – Implementation 2

```
int binarySearch(int arr[], int item, int beg, int end) {  
    if (end >= beg) {  
        int midIndex = beg + (end - beg) / 2;  
        if (arr[midIndex] == item)  
            return midIndex;  
        if (arr[midIndex] < item)  
            return binarySearch(arr, item, beg, midIndex - 1);  
        return binarySearch(arr, item, midIndex + 1, end);  
    }  
    return -1;  
}
```

# Selection Sort Algorithm

# What is Selection Sort?

- It is a simple sort algorithm that revolves around the 'comparison'.
- In each iteration, one element gets placed.
- We choose the minimum element in the array and place it at the beginning of the array by swapping with the front element.
- We can also do this by choosing maximum element and placing it at the rear end.
- Selection sort basically selects an element in every iteration and places it at the appropriate position.

# Selection Sort - Algorithm

```
selectionSort(arr, n)
    iterate (n - 1) times
    set the first unsorted element index as the min
    for each of the unsorted elements
        if element < currentMin
            set element's index as new min
    swap element at min with first unsorted position
end selectionSort
```

# Selection Sort - Demonstration

Input:

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 23 | 10 | 16 | 11 | 20 |

First step - marking of sorted part

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 23 | 16 | 11 | 20 |

After i=1

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 11 | 16 | 23 | 20 |

## Selection Sort - Demonstration Cont.

After i=2

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 11 | 16 | 23 | 20 |

After i=3

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 11 | 16 | 20 | 23 |

After i=4, no iteration is required as the last element is already sorted

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 11 | 16 | 20 | 23 |

# Selection Sort - Implementation

```
void selectionSort(int arr[], int size) {  
    for (int j = 0; j < size - 1; j++) {  
        int min = j;  
        for (int i = j + 1; i < size; i++) {  
            if(arr[i]<arr[min])  
                min = i;  
        }  
        int tmp = arr[j];  
        arr[j] = arr[min];  
        arr[min] = tmp;  
    }  
}
```

# Insertion Sort Algorithm

# What is Insertion Sort?

- It is one of the easiest and brute force sorting algorithms
- Insertion sort is used to sort elements in either ascending or descending order
- In insertion sort, we maintain a sorted part and unsorted part
- It works just like playing cards i.e picking one card and sorting it with the cards that we have in our hand already which in turn are sorted
- With every iteration, one item from unsorted is moved to the sorted part
- First element is picked and considered as sorted
- Then we start picking from 2nd elements onwards and start comparison with elements in sorted part.
- We shift the elements from sorted by one element until an appropriate location is not found for the picked element
- This continues till all the elements get exhausted

# Insertion Sort - Algorithm

```
insertionSort(arr, size)
```

```
    consider 1st element as sorted part
```

```
    for each element from i=2 to n-1
```

```
        tmp = arr[i]
```

```
        for j=i-1 to 0
```

```
            If  $a[j] > tmp$ 
```

```
                Then right shift it by one position
```

```
            put tmp at current j
```

# Insertion Sort - Demonstration

input:

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 23 | 10 | 16 | 11 | 20 |

First step - marking of sorted part

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 23 | 10 | 16 | 11 | 20 |

After i=1

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 23 | 16 | 11 | 20 |

After i=2

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 10 | 16 | 23 | 11 | 20 |

## Insertion Sort - Demonstration Cont.

After  $i=3$

| 0  | 1  | 2  | 3  | 4  |
|----|----|----|----|----|
| 10 | 11 | 16 | 23 | 20 |

After  $i=4$

| 0  | 1  | 2  | 3  | 4  |
|----|----|----|----|----|
| 10 | 11 | 16 | 20 | 23 |

# Insertion Sort - Implementation

```
void insertionSort(int arr[], int size) {  
    for (int i = 1; i < size; i++) {  
        int tmp = arr[i];  
        int j = i - 1;  
        while (j >= 0 && tmp < arr[j]) {  
            arr[j + 1] = arr[j];  
            --j;  
        }  
        arr[j + 1] = tmp;  
    }  
}
```

# Quick Sort Algorithm

# What is Quick Sort?

- It is one of the most widely used sorting algorithm
- It follows divide and conquer paradigm
- Recursion is used in quicksort implementation
- In each recursive call, a pivot is chosen then the array is partitioned in such a way that all the elements less than pivot lie to the left and all the elements greater than pivot lie to the right
- After every call, the chosen pivot occupies its correct position in the array which it is supposed to as in sorted array
- So with each step, our problem gets reduced by 2 which leads to quick sorting
- Pivot can be an element. Example: last element of current array, first element of current array, random pivot, etc.

# Quick Sort - Algorithm

```
quickSort(arr, beg, end)
    if (beg < end)
        pivotIndex = partition(arr, beg, end)
        quickSort(arr, beg, pivotIndex - 1)
        quickSort(arr, pivotIndex + 1, end)
```

# Partition - Algorithm

```
partition(arr, beg, end)
    set end as pivotIndex
    pIndex = beg - 1
    for i = beg to end-1
        if arr[i] < pivot
            swap arr[i] and arr[pIndex]
            pIndex++
    swap pivot and arr[pIndex+1]
    return pIndex + 1
```

# Quick Sort - Demonstration

Input:

|   |    |   |   |   |
|---|----|---|---|---|
| 0 | 1  | 2 | 3 | 4 |
| 5 | 10 | 9 | 6 | 7 |

beg

pivot, end

Step 1

|   |   |   |    |   |
|---|---|---|----|---|
| 0 | 1 | 2 | 3  | 4 |
| 5 | 6 | 7 | 10 | 9 |

beg

pivot, end

beg

pivot, end

Step 2

|   |   |   |   |    |
|---|---|---|---|----|
| 0 | 1 | 2 | 3 | 4  |
| 5 | 6 | 7 | 9 | 10 |

beg,pivot,end

beg,pivot, end

# Quick Sort - Implementation

```
void quickSort(int[] a,int p,int r)
{
    if(p<r)
    {
        int q=partition(a,p,r);
        quickSort(a,p,q-1);
        quickSort(a,q+1,r);
    }
}
```

## Quick Sort – Implementation Cont.

```
int partition_function(int arr[], int l, int h){  
    int pivot = arr[h]; // pivot is the last element  
    int pIndex = (l - 1); // Index of smaller element  
    for (int j = l; j <= h- 1; j++){  
        if (arr[j] < p){  
            i++;  
            swap_elements(&arr[i], &arr[j]);  
        }  
    }  
    swap_elements(&arr[i + 1], &arr[h]);  
    return (i + 1);  
}
```

# Merge Sort Algorithm

# What is Merge Sort?

- In merge sort, the problem is divided into two sub problems in every iteration
- Hence efficiency is increased drastically
- It follows divide and conquer approach
- Divide break the problem into 2 sub problem which continues until problem set is left with one element only
- Conquer basically merges the 2 sorted array into the original array

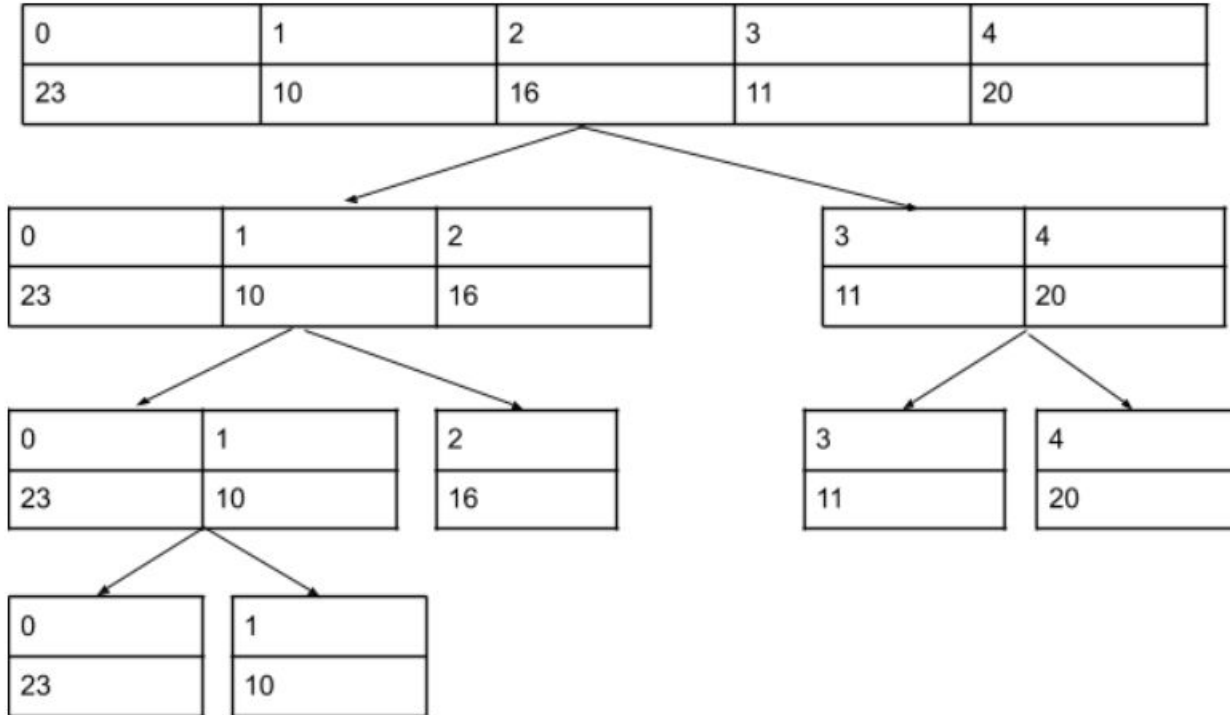

# Merge Sort - Algorithm

```
mergeSort(arr, left, right)
  if left > right
    return
  mid = (left+right)/2
  mergeSort(arr, left, mid)
  mergeSort(arr, mid+1, right)
  merge(arr, left, mid, right)
end
```

# Merge Sort - Demonstration

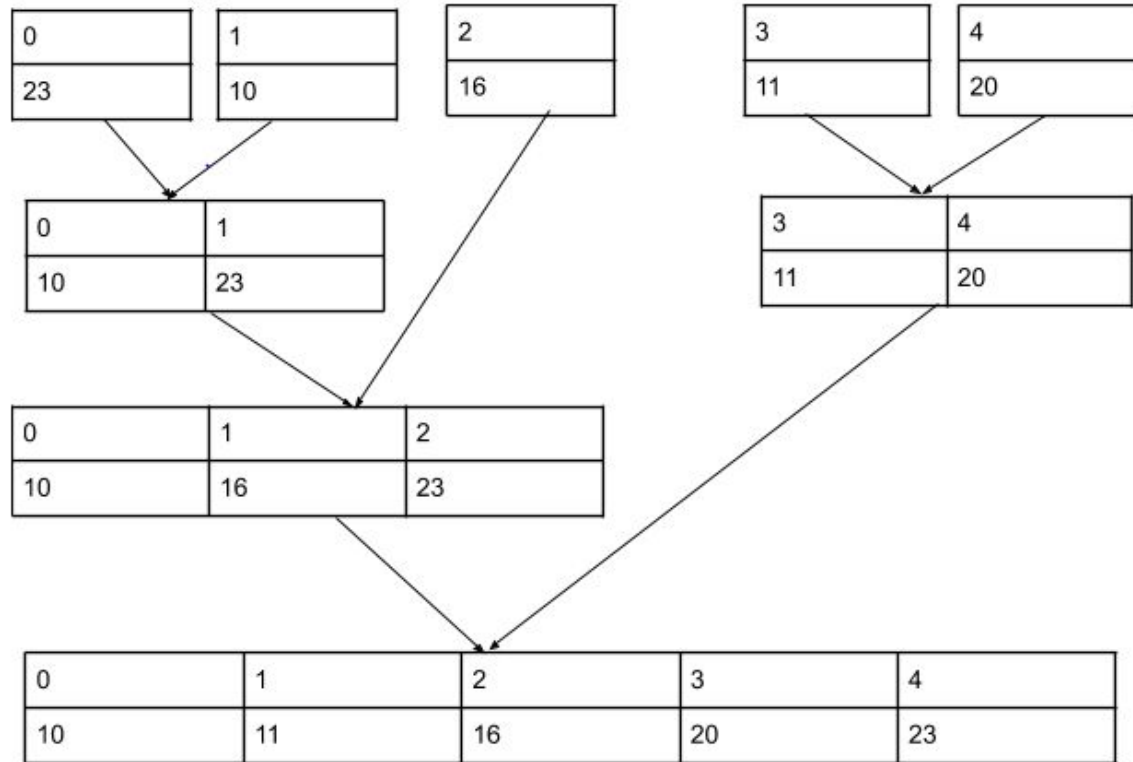

# Merge - Algorithm

- Create 2 subarrays Left and Right
- Create 3 iterators i, j and k
- Insert elements in Left and Right ( i & j)
- k - Replace the values in the original array
- Pick the larger elements from Left and Right & place them in the correct position
- If there are no elements in either Left or Right, pick up the remaining elements either from Left or Right and insert in original array

## Merge - Demonstration

# Merge Sort - Implementation

```
void mergeSort(int arr[], int start, int right) {  
    if (start < right) {  
        int mid = (start + right) / 2;  
        mergeSort(arr, start, mid);  
        mergeSort(arr, mid + 1, right);  
        merge(arr, start, mid, right);  
    }  
}
```

## Merge Sort – Implementation Cont.

```
void merge(int arr[], int start, int mid, int end) {
```

```
    int len1 = mid - start + 1;
```

```
    int len2 = end - mid;
```

```
    int leftArr[len1], rightArr[len2];
```

```
    for (int i = 0; i < len1; i++)
```

```
        leftArr[i] = arr[start + i];
```

```
    for (int j = 0; j < len2; j++)
```

```
        rightArr[j] = arr[mid + 1 + j];
```

## Merge Sort – Implementation Cont.

```
int i, j, k;  
i = 0;  
j = 0;  
k = start;  
while (i < len1 && j < len2) {  
    if (leftArr[i] <= rightArr[j]) {  
        arr[k] = leftArr[i];  
        i++;  
    } else {  
        arr[k] = rightArr[j];  
        j++;  
    }  
    k++;  
}
```

## Merge Sort – Implementation Cont.

```
while (i < len1) {  
    arr[k] = leftArr[i];  
    i++;  
    k++;  
}  
while (j < len2) {  
    arr[k] = rightArr[j];  
    j++;  
    k++;  
}  
}
```

# Quick Sort Vs Merge Sort

| <u>QUICK SORT</u>                                                                       | <u>MERGE SORT</u>                             |
|-----------------------------------------------------------------------------------------|-----------------------------------------------|
| Splitting of array depends on the value of pivot and other array elements               | Splitting of array generally done on half     |
| Worst case time complexity is $O(n^2)$                                                  | Worst case time complexity is $O(n \log n)$   |
| It takes less n space than merge sort                                                   | It takes more n space than quick sort         |
| It work faster than other sorting algorithms for small data set like Selection sort etc | It has a consistent speed on any size of data |
| It is in-place                                                                          | It is out-place                               |
| Not stable                                                                              | Stable                                        |
